Oat stem rust, caused by *Puccinia graminis* f. sp. *avenae* Eriks. & E. Henn. (*Pga*), can reduce yield and quality in oat, *Avena sativa* L. (Roelfs and Long 1980). Resistance breeding has been used as a cost-effective strategy to prevent these losses. There are currently 17 numbered oat stem rust resistance genes (*Pg*), and one gene complex known as *Pg-a*. Twelve of the numbered *Pg* genes are used as standard differentials to identify pathogenic races of *Pga* (Fetch Jr. and Jin 2007). While RFLP and RAPD markers for *Pg9* and *Pg13* have been previously reported (O'Donoughue et al. 1996), there has been no systematic search for markers linked to all known *Pg* genes. Objectives of this study were to 1) generate crosses of each standard differential and the *Pg-a* complex in two susceptible genetic backgrounds, and 2) find SNP markers linked to resistance using bulked segregant analysis.

Accessions with *Pg8* (Clav 9321; with Rodney 0 background) and the *Pg-a* complex (Clav 9339) were crossed to the susceptible *A. sativa* cultivars ‘Marvellous’ and ‘Otana’. *A. strigosa* accession Clav 6956 with *Pg6* was crossed with the susceptible *A. strigosa* accessions Clav 2524 and PI 573582. Populations were advanced to F2:3 and 10 seedlings from each of 70 families, parents, and F1s were inoculated with *Pga* race KBD (virulent to *Pg2*, *Pg3*, *Pg4*, and *Pg15* and avirulent to *Pg1*, *Pg6*, *Pg8*, *Pg9*, *Pg10*, *Pg12*, *Pg13*, *Pg16* and the *Pg-a* complex). Homozygosity in the F2:3 families was verified in the F2:4. F1s obtained from crosses with the *Pg6*, *Pg8* and *Pg-a* complex were resistant, indicating dominant inheritance. A 1:1 segregation ratio of homozygous F2:3 families in the ‘Otana’/*Pg6* and ‘Otana’/*Pg8* crosses indicated the presence of a single dominant resistant gene. The segregation ratio of 2 resistant to 1 susceptible F2:3 families in the ‘Otana’/*Pg-a* was not consistent with previous work that concluded the *Pg-a* complex consisted of the recessive *Pg12*, and at least one other recessive *Pg* gene (Fetch Jr. 2006). The parents, F1s, and families that were homozygous for susceptibility from the ‘Otana’/*Pg8*, ‘Otana’/*Pg-a*, and PI 573582/*Pg6* crosses were genotyped with the Illumina Oat Consortium 6K SNP BeadArray. Markers linked to resistance will be identified when genotyping data are available. Marker information obtained from this project can be used to identify new *Pg* resistance (Steinberg et al. 2005), and facilitate selection of progeny with multiple resistant genes.
